

FEATURES

- Outstanding Gain Linearity
- Ultrahigh Gain 5000 V/mV Min
- Low V_{OS} Over Temperature 60 μV Max
- Excellent TCV_{OS} 0.3 $\mu\text{V}/^\circ\text{C}$ Max
- High PSRR 3 $\mu\text{V}/\text{V}$ Max
- Low Power Consumption 60 mW Max
- Fits OP07, 725, 108A/308A, 741 Sockets
- Available in Die Form

PIN CONNECTIONS

Epoxy Mini-Dip (P-Suffix)
8-Pin Hermetic DIP

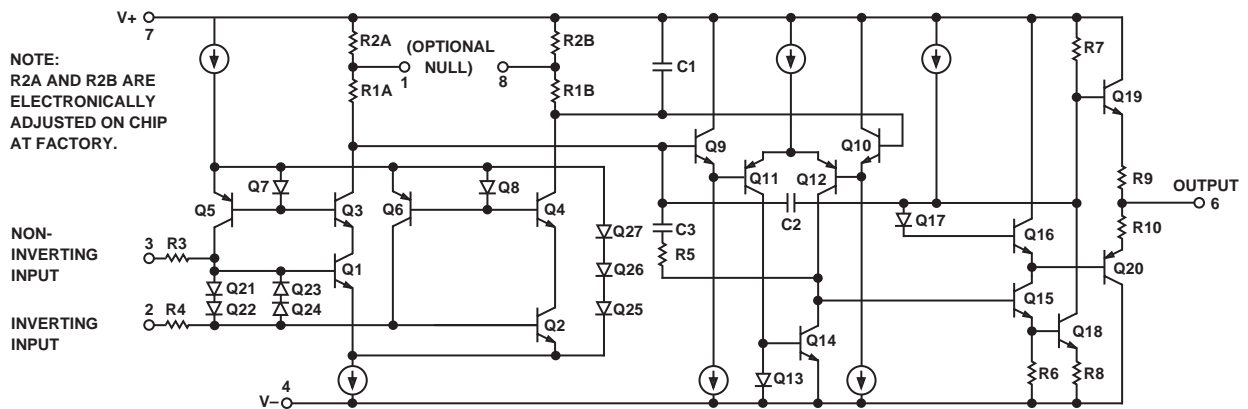

TO-99 (J-Suffix)

GENERAL DESCRIPTION

The OP77 significantly advances the state-of-the-art in precision op amps. The OP77's outstanding gain of 10,000,000 or more is maintained over the full 10 V output range. This exceptional gain-linearity eliminates incorrectable system nonlinearities common in previous monolithic op amps, and provides superior performance in high closed-loop gain applications. Low initial V_{OS} drift and rapid stabilization time, combined with only 50 mW power consumption, are significant improvements over previous designs. These characteristics, plus the exceptional TCV_{OS} of 0.3 $\mu\text{V}/^\circ\text{C}$ maximum and the low V_{OS} of 25 μV maximum, eliminates the need for V_{OS} adjustment and increases system accuracy over temperature.

PSRR of 3 $\mu\text{V}/\text{V}$ (110 dB) and CMRR of 1.0 $\mu\text{V}/\text{V}$ maximum virtually eliminate errors caused by power supply drifts and common-mode signals. This combination of outstanding characteristics makes the OP77 ideally suited for high-resolution instrumentation and other tight error budget systems.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the OP77 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

Figure 4. Burn-In Circuit

- NOTES
1. GAIN NOT CONSTANT. CAUSES NONLINEAR ERRORS.
 2. A_{VO} SPEC IS ONLY PART OF THE SOLUTION.
 3. CHECK THE OP AMP PERFORMANCE, ESPECIALLY AT TEMPERATURES.

Figure 5. Open-Loop Gain Linearity

Actual open-loop voltage gain can vary greatly at various output voltages. All automated testers use endpoint testing and therefore only show the average gain. This causes errors in high closed-loop gain circuits. Since this is so difficult for manufacturers to test, users should make their own evaluation. This simple test circuit makes it easy. An ideal op amp would show a horizontal scope trace.

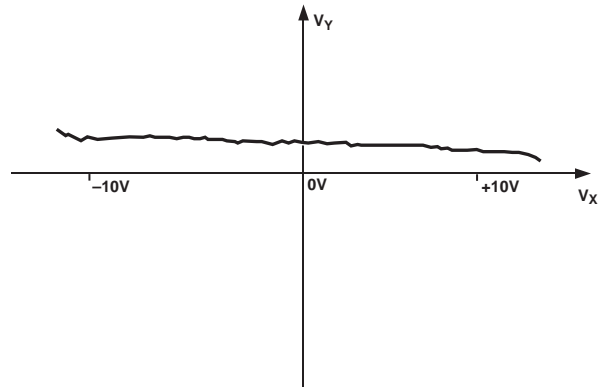

Figure 6. Output Gain Linearity Trace

This is the output gain linearity trace for the new OP77. The output trace is virtually horizontal at all points, assuring extremely high gain accuracy. The average open-loop gain is truly impressive—approximately 10,000,000.

APPLICATIONS INFORMATION

Bilateral Current Source

Figure 7. Precision High-Gain Differential Amplifier

The high gain, gain linearity, CMRR, and low TCVs of the OP77 make it possible to obtain performance not previously available in single-stage very high-gain amplifier applications.

For best CMR, $\frac{R1}{R2}$ must equal $\frac{R3}{R4}$. In this example,

with a 10 mV differential signal, the maximum errors are as listed in Table I.

Table I. Maximum Errors

TYPE	AMOUNT
COMMON-MODE VOLTAGE	0.01%/V
GAIN LINEARITY, WORST CASE	0.02%
TCVOS	0.003%/°C
TCIOS	0.008%/°C

Figure 8. Isolating Large Capacitive Loads

This circuit reduces maximum slew-rate but allows driving capacitive loads of any size without instability. Because the boom resistor is inside the feedback loop, its effect on output impedance is reduced to insignificance by the high open-loop gain of the OP77.

Figure 9. Basic Current Source

$$I_{OUT} = V_{IN} \left(\frac{R3}{R1 - R5} \right)$$

GIVEN $R3 = R4 + R5, R1 = R2$

Figure 10. 100 mA Current Source

These current sources will supply both positive and negative current into a grounded load.

Note that $Z_O = \frac{R5 \left(\frac{R4}{R2} + 1 \right)}{R5 + R4} \frac{R3}{R1}$

and that for Z_O to be infinite,

OP77

$$\frac{R5 + R4}{R2} \text{ must} = \frac{R3}{R1}$$

Precision Current Sinks

Figure 11. Positive Current Sink

Figure 12. Positive Current Source

These simple high-current sinks require the load to float between the power supply and the sink.

In these circuits, OP77's high gain, high CMRR, and low TCV_{OS} ensure high accuracy.

Figure 13. High Stability Voltage Reference

This simple bootstrapped voltage reference provides a precise 10 V virtually independent of changes in power supply voltage, ambient temperature and output loading. Correct Zener operating current of exactly 2 mA is maintained by R1, a selected 5 ppm/°C resistor, connected to the regulated output. Accuracy is primarily determined by three factors: the 5 ppm/°C temperature coefficient of D1, 1 ppm/°C ratio tracking of R2 and R3, and operational amplifier V_{OS} errors.

V_{OS} errors, amplified by 1.6 (AV_{CL}), appear at the output and can be significant with most monolithic amplifiers. For example, an ordinary amplifier with TCV_{OS} of 5 $\mu V/^\circ C$ contributes 0.8 ppm/°C of output error while the OP77, with TCV_{OS} of 0.3 $\mu V/^\circ C$, contributes but 0.05 ppm/°C of output error, thus effectively eliminating TCV_{OS} as an error consideration.

The high gain and low TCV_{OS} assure accurate operation with inputs from microvolts to volts. In this circuit, the signal always

Figure 14. Precision Absolute Value Amplifier

The high gain and low TCV_{OS} assure accurate operation with inputs from microvolts to volts. In this circuit, the signal always

appears as a common-mode signal to the op amps. The OP77E CMRR of 1 $\mu V/V$ assures errors of less than 2 ppm.

Figure 15. Low Noise Precision Reference

This circuit relies upon OP77's low TCV_{OS} and noise combined with very high CMRR to provide precision buffering of the averaged REF01 voltage outputs.

C_H must be of polystyrene, Teflon*, or polyethylene to minimize dielectric absorption and leakage. The droop rate is determined by the size of C_H and the bias current of the AD820.

*Teflon is a registered trademark of the Dupont Company

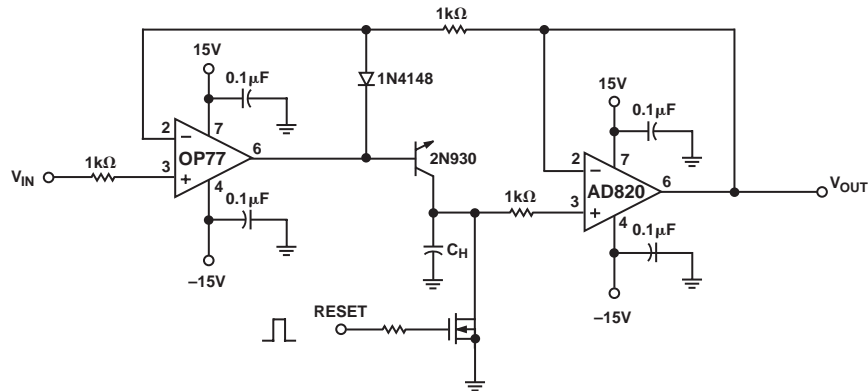

Figure 16. Precision Positive Peak Detector

OP77

Figure 17. Precision Threshold Detector/Amplifier

When $V_{IN} < V_{TH}$, amplifier output swings negative, reverse biasing diode D1. $V_{OUT} = V_{TH}$ if $R_L = \infty$ when $V_{IN} > V_{TH}$, the loop closes,

$$V_{OUT} = V_{TH} + (V_{IN} - V_{TH}) \left(1 + \frac{R_F}{R_S} \right)$$

C_C is selected to smooth the response of the loop.
